September 8, 2007 has been proclaimed as World Rabies Day by the Alliance for Rabies Control. The purpose of World Rabies Day is to focus attention on this entirely preventable cause of worldwide death and suffering. Over 55,000 human rabies deaths occur annually, mostly in Africa and Asia. Worldwide, there are more rabies deaths than for polio, diphtheria, and yellow fever combined.

The most important global source of rabies in humans is from uncontrolled rabies in dogs. This major cause of rabies in humans can be eliminated. As demonstrated decades ago, comprehensive and coordinated rabies vaccination of dog populations will result in local extinction of dog-associated strains or types of rabies viruses, especially if coupled with population management and novel approaches for hard-to-reach animals. When rabies is eliminated in the main animal reservoir, human exposures from this source no longer occur.

Human rabies is rare in the United States due to the elimination of endemic dog variant rabies and the use of effective, modern biologics for those individuals exposed to rabid or suspected rabid animals. Over 6,000 cases of wildlife rabies, primarily in bats, raccoons, skunks, and foxes, still exist in the U.S. and these result in human and animal exposures requiring thousands of human rabies post-exposure treatments and thousands of animal euthanasias or quarantines.

The personal impact of rabies can be enormous, as the bite of a rabid dog can lead to months of anxiety while victims are unsure as to whether rabies may develop. This is particularly true for poor people living in rural areas of Africa and Asia where post-exposure vaccines and immunoglobulin may not be available and are very expensive. Children are often at greatest risk from rabies as they are more likely to be bitten by dogs, and are also more likely to be bitten in high-risk sites on the body, such as the head and neck. Also, because rabies affects the brain, its victims often have frightening symptoms starting several weeks to months after an exposure. A person may feel strange sensations at the site of the bite from a rabid animal, hallucinations, difficulty swallowing and probably most notoriously, hydrophobia (fear of water) – all of which are quickly followed by death. There is no known medical cure once clinical signs of rabies are present. The bite of rabid animals often causes terrible injuries even if rabies itself can be prevented by effective post-exposure prophylaxis.

In addition, rabies is a concern for animal welfare. Fear of the disease may result in hostile and antagonistic attitudes towards dogs and often inhumane approaches to rabies control among dogs in a community. Also, rabies poses an immediate threat to several of the world's most endangered wildlife populations, such as the Florida Panther, Ethiopian wolf, and African Wild Dog.

The Centers for Disease Control and Prevention (CDC) is holding a one-day conference on the state of rabies research, control, and prevention for World Rabies Day. Other national and interna-

First Steps to Lifelong Success
Program provides support for children with developmental disabilities or delays
Kirsten Hammock, B.A., Part C Coordinator, First Steps Program, Early Childhood Development Branch

The First Steps program is Kentucky’s response to Part C of the Individuals with Disabilities Education Improvement Act (IDEA) of 2004. First Steps provides support and services to infants and toddlers with developmental disabilities and/or delays and their families. In Kentucky, the Department for Public Health (DPH) is the lead agency responsible for administering the First Steps program. During FY06, the First Steps program served more than 11,000 children and families statewide.

To be eligible for the First Steps program, Kentucky infants or toddlers must be between the ages of birth and three years and have a diagnosed physical or mental condition that has a high probability of resulting in a developmental delay or must be exhibiting a developmental delay in one or more of the following areas:

- Assistive technology
- Audiology
- Developmental intervention (special instruction)
- Health and/or medical diagnostic services (limited)
- Occupational therapy
- Physical therapy
- Psychological services
- Social work services
- Speech-language pathology services; and/or vision services

First Steps services are designed to support families during their daily routines and activities in their home and in the places where their child typically spends his/her day. Supporting and nurturing the caregiver-child relationship is a primary goal of the First Steps program because intervention is most successful when incorporated into natural learning.

All Kentucky infants and toddlers with suspected developmental concerns may receive a free evaluation to determine if they are eligible for the program. Eligible infants and toddlers may also receive one or more assessments for program planning purposes and service coordination at no cost to the family. First Steps services like developmental intervention, physical therapy and/or speech and language therapy are provided for a small charge, but are available at no cost to families who cannot pay. Families who have private insurance are encouraged to allow First Steps providers to bill their insurance in order to offset the cost of services. However, private insurance use is not required.
activities carried out by trusted and caring parents and caregivers. While First Steps offers a wide array of professional services, it is the parents and caregivers who provide the real intervention by creatively adapting their child care methods to enhance the development of their child.

The First Steps program utilizes a consultative model of service delivery. In contrast to a direct services model or a medical model in which an interventionist works directly with a child while the caregiver passively observes or even leaves the room, a consultative model views the caregiver as the primary focus of the intervention. In a consultative model, the interventionist provides the caregiver with strategies to embed intervention into everyday routines and activities, whereby increasing the number of opportunities the child has during a given day to practice one or more new skills across a variety of activities and settings.

Primary referral sources are responsible for referring infants and toddlers who they suspect may be eligible for First Steps services to the First Steps program as soon as possible after they are identified. Primary referral sources include physicians, childcare programs, schools, public health providers, and other health and social service providers. Primary referral sources, families, and other interested parties access the First Steps program locally through 15 system Points of Entry (POEs) covering the 15 Area Development Districts (ADDs). To find the Point of Entry in any ADD, interested parties may call 1-800-442-0087.

POEs are responsible for receiving referrals for all infants and toddlers with suspected developmental concerns and providing initial service coordination. Initial service coordinators (ISCs) assist families by arranging for evaluations to determine eligibility and coordinating the development of individualized family service plans (IFSPs) for eligible children and families.

Once an IFSP is developed, a primary service coordinator (PSC) is selected who is responsible for coordinating support of the child and family’s services throughout their participation in First Steps. The PSC will ensure that the IFSP is reviewed on a regular basis, that support and services respond to the changing needs of the child and family, and that the child and family are adequately prepared to leave the program at age three.

The U.S. Department of Education (DOE) has recently been focusing attention on child outcomes and is interested to know what progress, if any, infants and toddlers have made as a result of participating in the Part C (First Steps) program. The U.S. DOE has established three outcomes related to early childhood development that states must measure progress toward. Those outcomes include: 1) Infants and toddlers have positive social-emotional skills, including social relationships; 2) Infants and toddlers acquire and use knowledge and skills, including early language/communication skills; and 3) Infants and toddlers use appropriate behaviors to meet their needs. Kentucky is currently in the process of collecting baseline child outcome data and should be prepared to begin reporting on child progress toward the U.S. DOE’s established child outcomes in February 2009.

For more information on the First Steps program, call (502) 564-3756 or log onto www.chfs.ky.gov/dph/firststeps.htm.

**Hip Fractures and Osteoporosis**

*Incidence of hip fracture increases with age - women at a higher risk than men*

Chandra Venettozzi, B.A., Office of Health Policy, Cabinet for Health and Family Services
Genie Prewitt, RN, MSN, Osteoporosis Program Manager/Nurse Consultant, Chronic Disease Prevention and Control Branch, Kentucky Department for Public Health

**Introduction**

Hip fracture is among the most common musculoskeletal injuries requiring surgical treatment in the U.S. and one of the most detrimental bone fractures one can endure. Data from the Kentucky Department for Public Health (DPH) indicate that one-fourth of individuals that suffer a hip fracture die within one year of the injury.

(Continued on Page 4)
A hip fracture can involve fractures of any aspect of the proximal femoral neck (just below the ball part of the ball and socket joint) and from the neck to the first 4-5 centimeters of the subtrochanteric area (outward-jutting upper femur).

The Impact of Hip Fracture
Hip fractures and their treatment have lasting health consequences beyond immediate hospital treatment. Only 25% of individuals who have sustained hip fractures will make a full recovery from their injury, with 50% needing a cane or walker and as many as 25% require nursing home care for at least a year due to their injury. Only 40% of patients are able to perform activities of daily living independently after their fracture. Hip fractures reduce life expectancy by 1.8 years, and up to 20% of people in the U.S. who have a hip fracture will die within a year of injury due to complications with surgery procedure and/or recovery period issues.

Along with the decline of bone strength, hip fracture incidence increases with age and women are at a higher risk than men. Women who are 5'8" or taller have twice the risk of suffering a hip fracture than women under 5'3". Rates for hip fractures increase exponentially with age among both sexes, doubling every 5 to 6 years past age 50. People ages 85 and over are 10 to 15 times more likely to have a hip fracture than people between ages 60 and 65.

Relationship of Osteoporosis and Hip Fractures
Osteoporosis is the principal cause of reduced bone strength. It is difficult to identify fractures attributable to osteoporosis, but fractures do occur as a result of the relationship of bone strength with skeletal loading. For instance, fractures do not occur until the loads encountered in the course of everyday activities or with specific episodes of trauma exceed the breaking strength of the bone. It has been estimated that 90% of proximal femur fractures among white women 65-84 years of age are related to osteoporosis. Although the incidence of hip fracture is less in men, about 80% of male hip fractures are presumed to be osteoporotic-related.

The Cost of Hip Fractures
Hip fractures are very costly for both individuals as well as Kentucky’s health care system. The average cost per patient for treating and caring for a hip fracture within the first year of occurrence is $26,912. National annual Medicare costs for the treatment of hip fractures were estimated to be $2.9 billion in 1991. Lifetime costs attributable to sustaining a hip fracture were $81,300, of which 44% was spent on nursing home care. The lifetime costs noted by the *Journal for the American Geriatric Society* for all hip fractures in the U.S. have been estimated as being greater than $20 billion.

Kentucky: Hip Fracture Hospitalizations and the Elderly
Selection criteria for this analysis included individuals with a principal diagnosis ICD-9 code of 820.0 through 820.9 with a corresponding diagnosis related group of 210, 211, 216, 217, 218, 230, 233, 234, or 236.

Kentucky hospital data for 2006 show there were 2,955 discharges of elderly patients with hip fracture from acute and rehabilitation hospitals. NOTE: Although most patients were likely to have been hospitalized only once during a year, it is possible that some may have had multiple discharges and been counted more than once. However, this occurs rarely in diagnosis of hip fractures. Table 1 (page 5) shows hospital discharges with diagnosis of hip fractures for individuals 65 years and over during that year.

Following national trends, females accounted for 75.5% of total hip fracture discharges while males make up 24.5%.

In 2000, there were a total of 2,673 admissions at acute care or rehabilitation hospitals for hip fractures. That number had increased to 2,955 by 2006. Figure 1 (page 5) shows the number of admissions per year by gender. In Kentucky’s female population 65 years and older, the incidence of hip fracture was 7.4 per 1000; in men the same age group, it was 3.4 per 1000. The rate per 1000 was 4.0 higher for women.

Figure 1. Hip Fractures by Year and Gender, Kentucky Years 2000-2006

The acute care or rehabilitation hospital emergency room was the chief admission source for hip fracture patients (both males and females in each age cohort). Physician referral was the next greatest source of admission to the hospital.

The average length of stay (ALOS) in an acute care or rehabilitation hospital for all cohorts regardless of admission source was 6.49 days. When the admission source was an emergency room the average length of stay was 5.79 days. Physician referral admissions had an average length of stay of 6.05 days. The longest stay was registered in the “transfer from a hospital” admission source with an average of 10.87 days. The length of stay has remained relatively stable since year 2000. Figure 2 (page 6) shows the average length of stay from years 2000 to 2006.
Table 2 shows discharges to placement after hospital care and the average length of stay for each male and female age cohort discharged (including deaths).

Within all age cohorts, most patients discharged from hospitals with hip fractures were placed in skilled nursing facilities (SNF). The ALOS ranged from a low of 6.04 days for females age 65-69 to a high of 7.17 days for males age 80-84 and does not vary widely by age group.

(Continued on Page 7)
Hip Fracture Risk Assessment

Risk factors identified for hip fractures include increasing age, environmental hazards, muscle weakness, functional limitations, use of psychoactive prescription drugs, and a history of previous falls. More than 95% of hip fractures are the result of a fall. The National Center for Injury Prevention and Control (NCIPC) recommends the following four strategies for an individual to help prevent falls:

1. Begin a regular exercise program, particularly with exercises which improve balance, coordination and strength, such as Tai Chi. Exercise is one of the most effective ways to decrease chances of falling and is low cost.

2. Have a home health care provider, primary doctor or pharmacist review all medications being taken (both prescription and over-the-counter) to ensure that there are no interactions that may cause dizziness or sleepiness, which can lead to falls.

3. Have a vision exam at least once a year by an optometrist.

4. Make sure the home is a safe place. Take the following steps to help decrease chances of falls occurring at home:
   - Remove items that can be tripped over such as shoes from areas that are often walked hallways or stairs.
   - Do not use small throw rugs or alternatively, use double-sided tape to ensure they will stay securely in place.
   - Store frequently used items in cabinets and closets, which do not require a step stool or are difficult to reach.
   - Have safety bars installed by the toilet and in the bathtub or shower.
   - Use non-slip mats in the bathtub/shower and on the bathroom floor.
   - Increase lighting in the home. Lightweight curtains or shades help reduce the glare of the sun while allowing more natural light naturally inside the house.
   - Place handrails and lights on all stairways.
   - Wear sturdy shoes both inside and outside of the house, as opposed to slippers or being barefoot.

For more information on helping to prevent falls, including a Home Fall Prevention Checklist for Older Adults, visit the National Center for Injury Prevention and Control at www.cdc.gov/ncipc.

Kentucky Intervention Program

To reduce the number of hip fractures for improved quality of life and increased longevity, DPH is working with other organizations to implement a new program called A Matter of Balance. This structured group program addresses physical, social, and cognitive factors affecting fear of falling and allows participants to learn fall prevention strategies. A Matter of Balance intervention program includes group discussion, problem-solving, skill building, assertiveness training, videotapes, sharing practical solutions and exercise training activities, as well as utilizing lay leaders to facilitate these classes. Twenty-one Kentucky master trainers completed the two-day session offered by Maine Health’s Partnership for a Healthy Aging and earned A Matter of Balance Master Trainer Certificate in May. Community programs will be implemented this fall in several regions in Kentucky and lay leaders will be trained to continue ongoing classes in community centers and faith-based organizations throughout Kentucky. It is important that health care professionals educate the elderly of the risk factors associated with hip fractures and ways they can prevent falls.

Conclusion

Hip fractures are an increasing concern for the elderly in terms of the extended time period spent in the hospital, high medical costs, and the probability that the individual may be placed in a skilled nursing facility upon discharge from the hospital. Falls in older adults are dangerous and preventable. Intervention programs that help older adults learn more about and minimize fall risks are important for maintaining independence. Evidence-based programs for the 60+ age population can have positive impact on the quality of life of Kentucky’s aging population.
For additional information on hip fractures and osteoporosis, contact the Department for Public Health’s Chronic Disease Branch at (502) 564-7996 or log onto www.chfs.ky.gov/dph/ach/cd/osteo.htm.
